

Close the self-starting handle control process

Note: The ROS_DOMAIN_ID of the Raspberry Pi and the microROS control board need to be consistent. You can check [MicroROS Control Board Parameter Configuration] to set the microROS control board ROS_DOMAIN_ID. Check the tutorial [Connect MicroROS Agent] to determine whether the IDs are consistent.

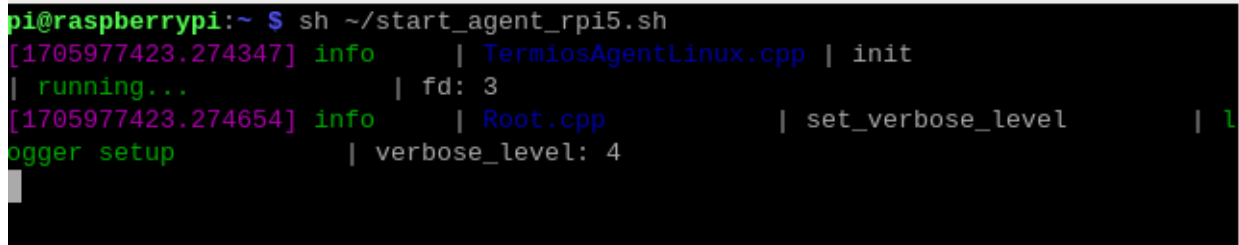

1. Program function description

The car connects to the agent, connects the handle's receiver to the Raspberry Pi 5 port, and enters docker. It provides methods for temporarily closing docker and permanently closing it.

2. Start and connect to the agent

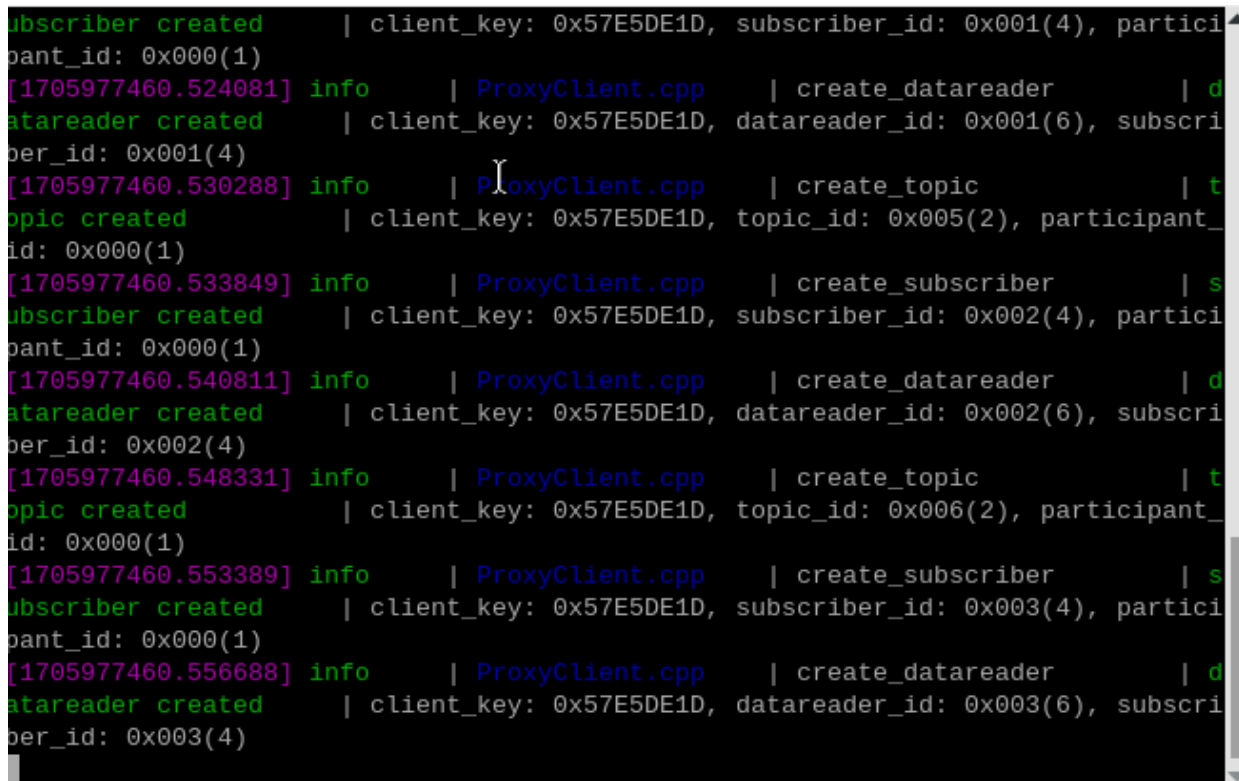

After successfully starting the Raspberry Pi, enter the following command to start the agent,

```
sh ~/start_agent_rpi5.sh
```

```
pi@raspberrypi:~ $ sh ~/start_agent_rpi5.sh
[1705977423.274347] info      | TermiosAgentLinux.cpp | init
| running...              | fd: 3
[1705977423.274654] info      | Root.cpp              | set_verbose_level      | 1
logger setup              | verbose_level: 4
```

Then, turn on the car switch and wait for the car to connect to the agent. The connection is successful, as shown in the figure below.

```

3. Enter the car docker

Open another terminal and enter the following command to enter docker:

```
sh ros2_humble.sh
```

When the following interface appears, you have successfully entered docker. Now you can control the car through commands.

```
pi@raspberrypi:~ $ ./ros2_humble.sh
access control disabled, clients can connect from any host
Successful
MY_DOMAIN_ID: 20
root@raspberrypi:/#
```

Enter the following command in the terminal to check whether the controller is mounted normally.

```
ls /dev/input*
```

When this interface appears, it means it was successfully mounted.

```
root@raspberrypi:/# ls /dev/input*
by-id      event0  event2  event4  event6  mice
by-path    event1  event3  event5  js0
root@raspberrypi:/#
```

4. Start the handle control program

4.1、Temporarily turn off the controller auto-start function

Because the handle control function has been automatically activated at boot, if we need to manually enable handle control, we need to turn off the auto-start process at boot. This is also a way to temporarily turn off the self-starting handle control.

Terminal input command:

```
ps -A
```

```
root@raspberrypi:/# ps -A
  PID TTY          TIME CMD
    1 pts/0        00:00:00 bash
    7 pts/0        00:00:00 bash
   68 ?            00:00:00 supervisord
  125 ?            00:00:00 sh
  126 ?            00:00:00 bash
  148 ?            00:00:00 python3
  170 ?            00:00:00 ros2
  171 ?            00:00:00 yahboom_joy
  173 ?            00:00:00 joy_node
  198 pts/0        00:00:00 ps
```

You can see that the processes of the handle control node and the handle node are 171 and 173. Turn off these two processes to manually start the handle control.

```
kill -9 171
kill -9 173
```

This will turn off the handle function.

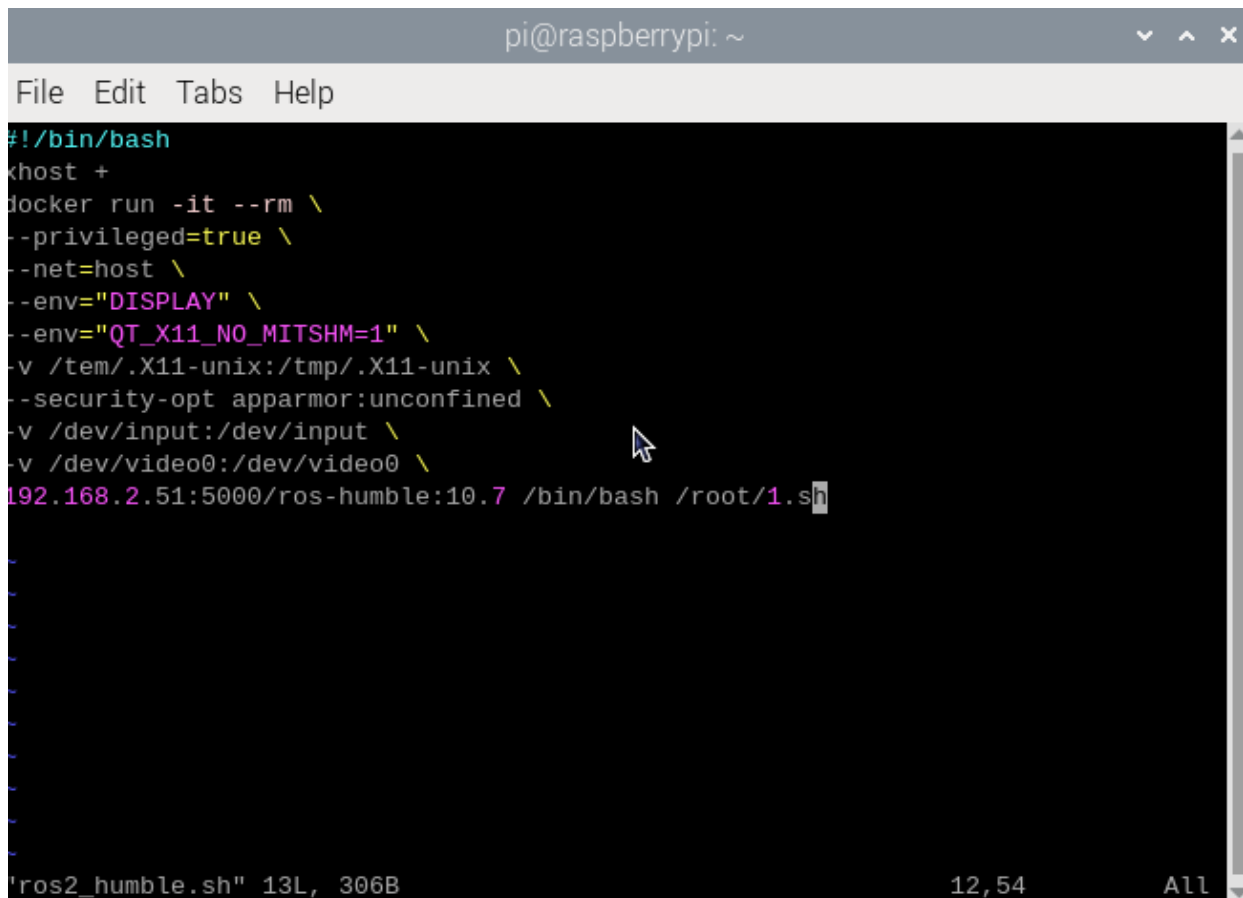

4.2. Permanently turn off the auto-start function of the handle

Permanently close the script file that needs to be modified into docker

Open a Raspberry Pi terminal and enter,

```
vi ros2_humble.sh
```

This interface appears

A screenshot of a terminal window titled 'pi@raspberrypi: ~'. The terminal shows a Docker command being entered: 'docker run -it --rm \'. The command continues with several options: '-privileged=true \', '-net=host \', '-env="DISPLAY" \', '-env="QT_X11_NO_MITSHM=1" \', '-v /tem/.X11-unix:/tmp/.X11-unix \', '-security-opt apparmor:unconfined \', '-v /dev/input:/dev/input \', and '-v /dev/video0:/dev/video0 \'. The command ends with '192.168.2.51:5000/ros-humble:10.7 /bin/bash /root/1.sh'. The terminal output shows the command being executed. The status bar at the bottom of the terminal window shows 'ros2_humble.sh' 13L, 306B, 12,54, and All.

To turn off the self-starting handle at boot, you only need to delete the /root/1.sh command. If you want to restore the self-starting handle after turning it off, just add it.

The script file in the picture below will not automatically start the controller control when the computer is turned on.

```
#!/bin/bash
xhost +
docker run -it --rm \
--privileged=true \
--net=host \
--env="DISPLAY" \
--env="QT_X11_NO_MITSHM=1" \
-v /tmp/.X11-unix:/tmp/.X11-unix \
--security-opt apparmor:unconfined \
-v /dev/input:/dev/input \
-v /dev/video0:/dev/video0 \
192.168.2.51:5000/ros-humble:10.7 /bin/bash
```
